

1. What is a Variable?

A **variable** is a named memory location used to store data in a program. The value stored in a variable can change during program execution. In Python, a variable is created automatically when a value is assigned to it.

```
name = "Thanuja"
```

```
age = 21
```

2. What are Identifiers?

An **identifier** is the name given to a variable, function, class, module, or any other object in Python. Identifiers help programmers refer to these objects in the program.

```
student_name = "Thanuja"
```

```
marks = 95
```

student_name and marks are identifiers.

3. What are Keywords?

Keywords are reserved words in Python that have predefined meanings and are used to define the syntax and structure of the language. They cannot be used as variable names, function names, or class names.

```
if
```

```
else
```

```
for
```

```
while
```

```
def
```

```
class
```

```
return
```

```
True
```

```
False
```

None

4. What are Literals?

Literals are fixed values written directly in a program. They represent constant values assigned to variables or used in expressions.

age = 21 # Integer literal

price = 99.99 # Float literal

name = "Python" # String literal

status = True # Boolean literal

5. What are the Rules for Naming Identifiers?

Python identifiers must follow these rules:

1. Must start with a letter (A–Z, a–z) or an underscore (_).
2. Cannot start with a number.
3. Can contain letters, digits, and underscores.
4. Cannot contain spaces.
5. Cannot use special characters such as @, #, \$, %.
6. Cannot use Python keywords.
7. Python identifiers are case-sensitive.
